(Dated: 13th August 2018)

If you get robbed and the only way to get your wallet or purse back is for police to determine the identity of the thief based on a blurry surveillance video of a moving suspect, you might wish that a computer can "calculate" a sharp and clear version of the required image which shows clearly who it is that has your money. This is more complicated than the simple face-recognition algorithms used by Facebook for automatic tagging, or by Google for image search, because it involves first predicting what the unblurry version of an image should look like, and may involve video footage rather than simply stationary photographs.

The state-of-the-art method for solving this problem in industry is by solving a QUBO problem, and some examples from the classical-computer QUBO literature are below:

QUBO based in-painting by from Ref. [1].

QUBO based in-painting by from Ref. [1].

QUBO based de-blurring from Ref. [2].

QUBO based de-noising from Ref. [3].

Therefore this is a real-world problem that is "perfect" for the D-Wave machines, because the industry standard for solving the problem is to run a QUBO optimization on a classical computer. Image de-noising is performed by detectives for recovering partial finger-prints, by museums for reconstructing antique paintings, and by doctors for medical imaging, but in these cases the number of pixels (and hence the number of binary variables in the QUBO problem) is small. For terabyte-sized telescope images of galaxies, inter-stellar media, and possible life-containing exo-planets, runtimes are colossal and we welcome any speed-up even if only by a constant factor of 10 or even 2.

The algorithm works by minimizing two functions of binary variables simultaneously:

$$f_C(X_C) = \sum_{i=1}^{K} \alpha_i \log(1 + \frac{1}{2}(J_i \cdot X_C)^2) \tag{1}$$

$$f_v(X_v) = \frac{(N_v - X_v)^2}{2\sigma^2} \tag{2}$$

---

* n.dattani@cfa.harvard.edu

The first function was calibrated by using billions of good and bad images such that the minimization of this function removes as much noise as possible. Minimizing the second function helps to maintain fidelity to the original image (its minimum occurs when the new pixel $N_v$ at location $v$ is the same as the original pixel $X_v$, but it is minimized simultaneously with Eq. 1 so our new pixels will not be exactly the same). $C$ denotes a clique of size $2 \times 2$, yielding 4-local interactions in the Hamiltonian. More accurate results can be obtained by using, for example, a $3 \times 3$ mask for the image processing, but this has never been applied in the literature since it would require quadratizing a 9-local Hamiltonian, which would greatly increase the number of auxiliary qubits required.

The number of binary variables (logical qubits) $Q_L$ is equal to the number of pixels in the image. At each iteration, we would either accept the pixel from $I$ or from $P$ depending on whether the variable associated with that pixel is 0 or 1. The clique terms in Eq. 1 are quartic. We used auxiliary qubits to quadratize this quartic function, and what we are left with is a quadratic unconstrained boolean optimization (QUBO) problem involving $Q_2$ qubits coupled at most quadratically. Once we have quadratized the problem into QUBO form, we can chimerize it so that it can run on D-Wave annealers. Efficient chimerization is an active area of research, with new methods being proposed frequently, however we estimate the number of physical qubits $Q_P$ needed by $\mathcal{O}(Q_2^2)$, which we know is an upper bound in the case for chimerizing a fully connected graph. Therefore, with $Q_A = 2048$ qubits available, we can have at least $Q_2 = 45$ qubits in the QUBO problem, so we will explore images of size $3 \times 3$ pixels ($Q_L = 9$ logical qubits) and $4 \times 4$ pixels ($Q_L = 16$ logical qubits). We do not investigate smaller images because the size of the image processing mask is $2 \times 2$. Below we show that the computer vision algorithm still works even for small images:

## I.  CHIMERIZATION OF A QUBO PROBLEM FOR DENOISING A $3 \times 3$ IMAGE

$$I = \begin{pmatrix} 201 & 180 & 195 \\ 183 & 209 & 210 \\ 173 & 171 & 162 \end{pmatrix} \quad P = \begin{pmatrix} 242 & 230 & 255 \\ 234 & 252 & 239 \\ 238 & 204 & 241 \end{pmatrix}$$

Initial number of binary variables (logical qubits): $Q_L = 9$.

Number of qubits after quadratization: 29

Graph connectivity for 29 spin Ising problem:
